

Slide 1

Hypoxia in the Gulf of Mexico

Nancy N. Rabalais
Louisiana Universities Marine Consortium
nrabalais@lumcon.edu

Slide 2

- Distribution and dynamics of hypoxia
 - What are the proximal causes?
 - What are the ultimate causes?
 - What has changed over time?
 - What are the consequences?
 - What are the solutions?

Slide 25

Slide 26

Slide 27

Is it Water (Physics)? or Nutrients (Biology)?

Modified from Rabalais et al. (2001)

Slide 28

There are clear signals that humans have altered the global cycles of nitrogen and phosphorus over large regions and increased the mobility and availability of these nutrients to marine ecosystems.

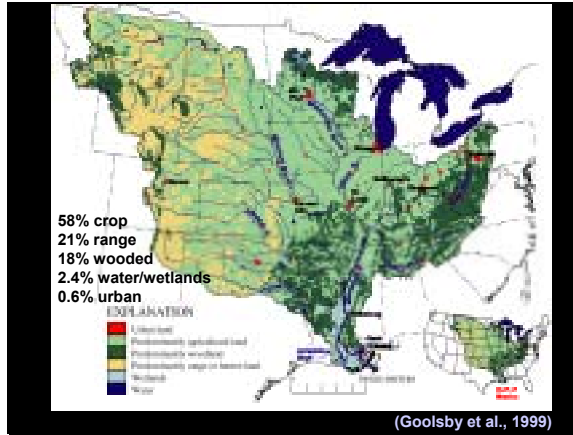

Slide 29

Slide 30

Slide 31

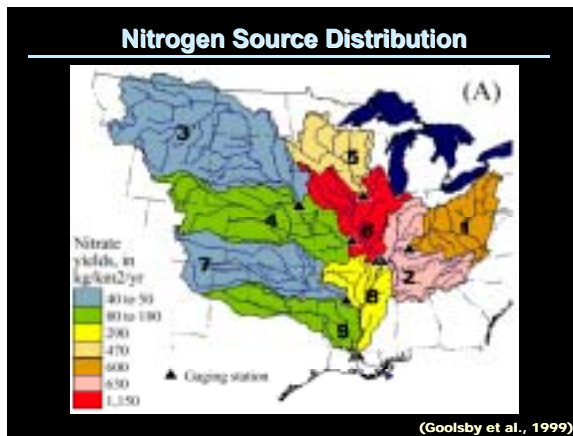

Slide 32

Nutrient concentrations and loads changed dramatically in the last half of the 20th century

- Riverine N and P tripled and doubled
- Spring nitrate peak now present
- Changes closely related to N and P fertilizer applications in watershed
- Offshore nutrient compositions shifted
- Water quality changes in nutrients, primarily, less in flow or delivery of flow

Slide 33

Work of Don Goolsby and his team.

Used USGS stream gage network and calculated Nitrate flux at a particular station – divided by the area of its watershed.

Nitrate Yield to be able to compare among different size watersheds

Highest Yields are from Illinois, Iowa, Indiana, southern Minnesota, and Ohio.

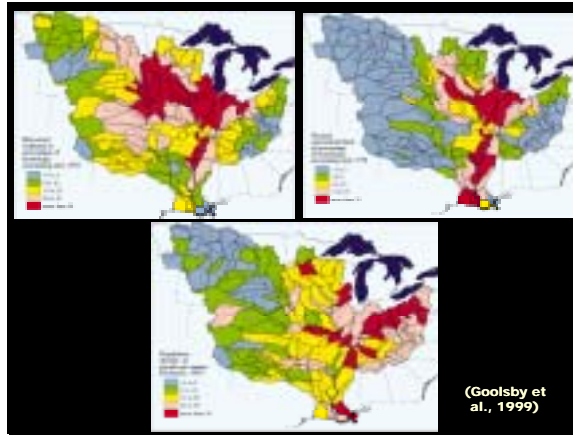

What's going on in those watersheds?

[CLICK](#)

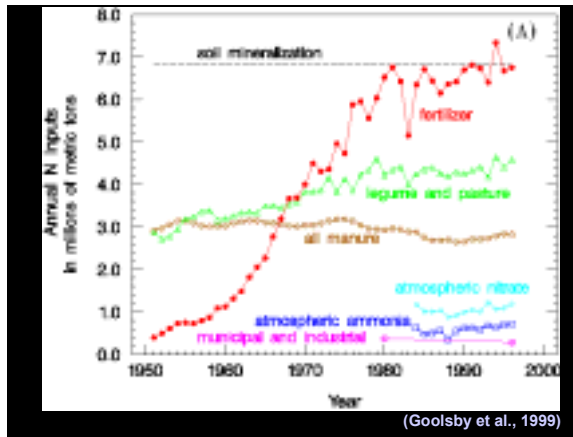

This is the primary area of lands drained for agricultural use. Goolsby's team looked at the relationships between yield and human activities across 32 sub-basins (at a finer scale than these 9).

Next Slide shows the key results.

The "Dead Zone" is

N. Rabalais

(© F. Viola, 1991)

..... not completely "dead."

O₂ > 2 mg/l

This slide features a collage of images. The top left shows a diver underwater in a dark, murky environment. The top right contains the text "The 'Dead Zone' is" and the name "N. Rabalais". The bottom left has the text "..... not completely 'dead.'" and the copyright notice "(© F. Viola, 1991)". The bottom right shows a close-up of fish in a shallow, turbid water column with the text "O₂ > 2 mg/l".

Slide 38

Effects of Hypoxia on Fisheries Resources

- Direct mortality
- Altered migration
- Reduction in suitable habitat
- Increased susceptibility to predation
- Changes in food resources
- Susceptibility of early life stages

K. St. Pê

(© F. Viola, 1991) (© F. Viola, 1991) (Rabalais et al., 2001)

This slide is titled "Effects of Hypoxia on Fisheries Resources". It includes a bulleted list of six effects: Direct mortality, Altered migration, Reduction in suitable habitat, Increased susceptibility to predation, Changes in food resources, and Susceptibility of early life stages. The name "K. St. Pê" is on the right. Three images are included: a dead fish on a beach, a yellowish worm-like organism, and a dark, textured mass. Copyright notices "(© F. Viola, 1991)", "(© F. Viola, 1991)", and "(Rabalais et al., 2001)" are at the bottom.

Slide 39

Stressed Benthos

Bacterial Mats

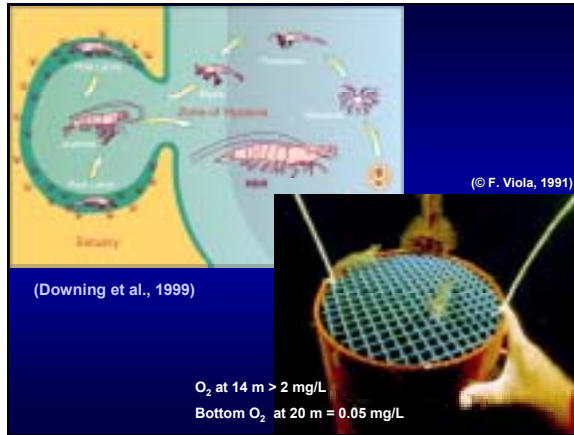

(© F. Viola, 1991) (© F. Viola, 1991)

This slide shows four images of benthic organisms. The top left image is labeled "Stressed Benthos" and shows a pale, worm-like creature. The top right image shows a starfish. The bottom left image shows a pinkish worm. The bottom right image shows a green, textured mat labeled "Bacterial Mats". Copyright notices "(© F. Viola, 1991)" are at the bottom of the images.

Slide 42

Slide 43

WHY DO WE CARE!

More nutrients – more primary production
– more fish

CLICK

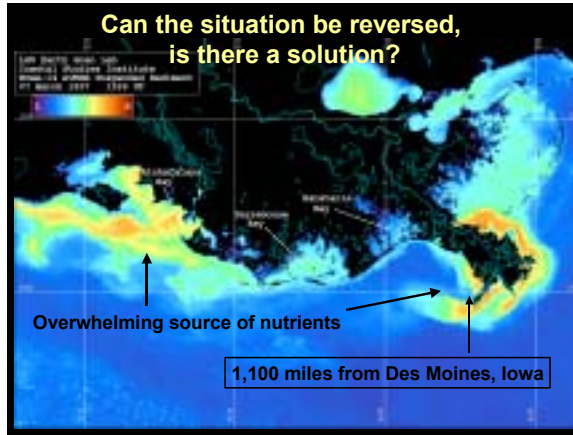

To a point. DESCRIBE THE GRAPH

Seasonal hypoxia begins to effect benthic community and demersal fish because of lost of favored habitat

this can (and has) led to collapsed fisheries.

\$64,000 question – where is the Gulf on this curve?

Slide 50

Gulf Action Plan: GOALS

- **Coastal.** By 2015, reduce hypoxia below 5,000 km².
- **Basin.** Restore and protect the waters of Basin States and Tribes.
- **Communities.** Improve social and economic conditions in the Basin.

- Aim to achieve a 30% reduction in N discharge to the Gulf, 5-yr running average
- Voluntary actions, incentives, education

COASTAL.

By 2015, reduce hypoxia below 5,000 km².
DOWN FROM 15,000.

Best science indicates that to get there will require about a 30% reduction in N load to the Gulf

BASIN.

Restore and protect the waters of Basin States and Tribes.

COMMUNITIES.

Improve social and economic conditions in the Basin.

Slide 51

Slide 52

Two key ways to reduce loads:

Decrease N loss from land

Increase Denitrification

When all is said and done, there are two key ways to reduce loads to surface waters.

CLICK

Decrease loss from the land – primarily agricultural, non-point sources

CLICK

Increase Denitrification. – a very important natural process that removes N from the biosphere.

Slide 53

Agricultural Non-Point Sources

	Nitrogen Reduction (1000 MT/yr)
 Farm N management Alt. crop systems	1,400 - 1,900 500
 Tertiary treatment (point sources)	20

(Mitsch et al.
Doering et al.)

CLICK

Mitsch and Doering estimated these N loss savngs:

FARM N MANAGEMENT would save 900,000 to 1.4 Million metric tons per year reduction in “insurance” rates of N fertilizer application, improved manure management, accounting for non-fertilizer nitrogen, when calculating application rates

CROPPING SYSTEMS – perennial instead of corn and soybeans rotation on about 10% of acreage – would save about 500,000 metric tons per year.

CLICK

For comparison, if municipal treatment plants went to tertiary treatment – that would yield about 20,000 Metric tons per year.

Slide 54

Bill Mitsch's team estimated that

Creating and Restoring 5 Million acres of wetland will remove 300,000 Metric Tons per year.

NOTE: that is 0.7 % of the basin.

It would take 19 million acres of Riparian Buffers to remove the same amount.

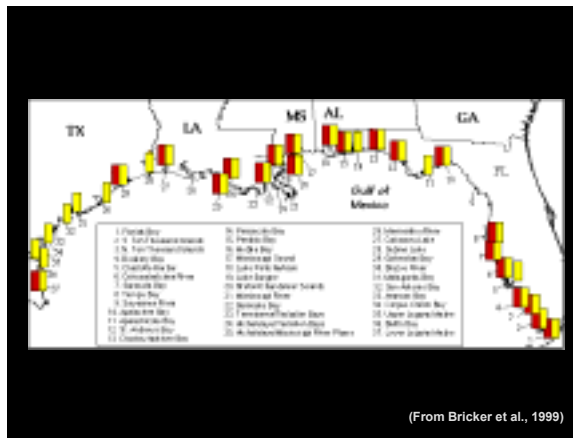

They also estimated that diverting 13% of the river flow over 1.2 M acres of coastal LA would remove 50,000 metric tons per year

AND help rebuilt coastal wetlands.

Slide 55

Slide 56

Slide 57

A National Problem

Over 60% of U.S. estuaries show high eutrophic conditions (Bricker et al., 1999)

Nutrient pollution is largest U.S. coastal pollution problem (NRC, 2000)

 = High Eutrophic Conditions

(From Bricker et al., 1999)

I want to close on a National Scale note.

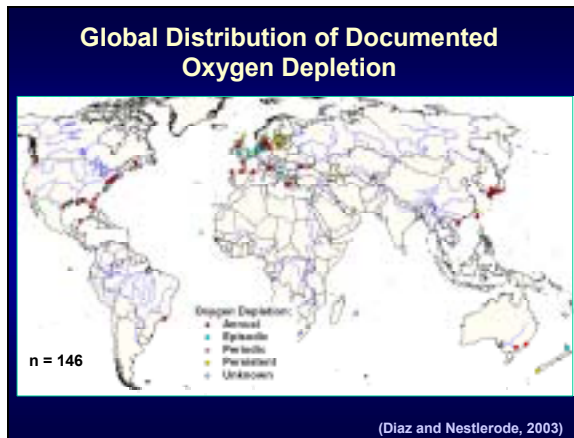

While many people are aware of nutrient pollution issues in the Chesapeake Bay, and now in the Gulf of Mexico, a recent NOAA report indicated that over 60% of our estuaries experience serious symptoms of eutrophication, including hypoxia.

GLICK

And the National Research Council, in their recent report – Clean Coastal Waters – state that Nutrient Pollution is the largest coastal pollution problem in the United States.

The problems in many of these places are similar and many of the solutions are comparable.

Slide 58

Slide 59

Hypoxia, Then & Now

- 44** (Diaz and Rosenberg, 1995)
- 50** (Science, 1998)
- 57** (Diaz and Rosenberg, 2000)
- 114** (Diaz, 2001)
- 146** (Diaz and Nestlerode, 2003)

Slide 60

Slide 61

- What do you predict with regard to distribution and severity of hypoxia, in the Gulf and elsewhere, with?
 - warming climate
 - doubled CO₂ atmospheric concentration
 - changes in freshwater inflow
 - frequency and severity of storms?
- How will fishery resources change?
